

Cheatsheet - Vectors

Fabio Lama – fabio.lama@pm.me

1. Intro

Quantities that can be described as single numbers (**magnitudes**) are known as **scalars**. Vectors are quantities that have a magnitude but also a **direction** and are represented as arrows, where the length represents the magnitude and the direction is given as points on a $x - y$ plane:

Here, the vector A to B is written as \vec{AB} (sometimes \underline{a} or \mathbf{a}), where A is the *tail* and B is the *head*. The **magnitude** of \vec{AB} is written as $|\vec{AB}|$ or \underline{a} .

Two vectors are **equal** if they have the same magnitude **and** the same direction.

A **unit vector** has magnitude of 1, written as $\hat{\mathbf{a}}$

2. Multiplying Vector by Scalar

$$\mathbf{a} = 4$$

$$3\mathbf{a} = 12$$

$$\frac{1}{2}\mathbf{a} = 2$$

Multiplying by a negative number **reverses** the direction, but the magnitude stays **positive**.

$$\mathbf{a} = 4$$

$$-3\mathbf{a} = 12$$

The unit vector of \mathbf{a} is given by:

$$\hat{\mathbf{a}} = \frac{1}{|\mathbf{a}|}\mathbf{a}$$

For example:

$$\mathbf{a} = 4$$

$$\hat{\mathbf{a}} = \frac{1}{4}\mathbf{a}$$

$$\mathbf{b} = \frac{1}{2}$$

$$\hat{\mathbf{b}} = \frac{1}{\frac{1}{2}}\mathbf{b} = 2\mathbf{b}$$

3. Adding and Subtracting Vectors

If \mathbf{a} and \mathbf{b} are two vectors then we can form the vector $\mathbf{a} + \mathbf{b}$. We take \mathbf{b} by its tail and move it to the head of \mathbf{a} while still maintaining magnitude and direction.

Or with more vectors:

When subtracting vectors, we consider that:

$$\mathbf{a} - \mathbf{b} = \mathbf{a} + (-\mathbf{b})$$

Therefore, we reverse the **direction** of **b** and move the tail of $-\mathbf{b}$ to the head of **a**.

Additionally:

TODO: Add clear rules for head/tail usage.

4. Cartesian Components

We have a $x - y$ plane, where unit vector of the x axis is \mathbf{i} and the unit vector of the y axis is \mathbf{j} .

We can see that:

$$\overrightarrow{OP} = \overrightarrow{OA} + \overrightarrow{AP}$$

$$\overrightarrow{OA} = 2\mathbf{i}$$

$$\overrightarrow{AP} = 4\mathbf{j}$$

$$\overrightarrow{OP} = 2\mathbf{i} + 4\mathbf{j}$$

The quantities 2 and 4 are **Cartesian components** of the vector \overrightarrow{OP} .

By using Pythagoras' theorem we can calculate the magnitude of \overrightarrow{OP} :

$$|\overrightarrow{OP}| = \sqrt{x^2 + y^2}$$

5. Scalar Product

We have already seen how to multiply a vector by a scalar (single number). To multiply a vector by a vector:

$$\mathbf{a} \times \mathbf{b} = |\mathbf{a}| \times |\mathbf{b}| \times \cos \theta$$

where θ is the angle between \mathbf{a} and \mathbf{b} . This scalar product is also know as the **dot product**.
